Introduction to Python

Why Python?

- High-level language, can do a lot with relatively little code

- Intuitive and easy to learn

- Has powerful programming features

- Interpreted: useful for development and testing

- Popular for Machine Learning

For More Information?

Python Hompage: http://python.org/

- documentation, tutorials, beginners guide, core distribution, ...

Books include:

- *Learning Python* by Mark Lutz

- *Python Essential* Reference by David Beazley

- *Python Cookbook*, by Martelli, Ravenscroft and Ascher
  (online at http://code.activestate.com/recipes/langs/python/)

- http://wiki.python.org/moin/PythonBooks

Development Environments

1. Anaconda (we will use this in the course)
   a) https://www.anaconda.com/

2. PyDev with Eclipse

3. Emacs

4. Vim

5. NotePad++ (Windows)

Important: We will use Python 3.x, not 2.x

(R)ead-(E)valuate-(P)rint-(L)oop
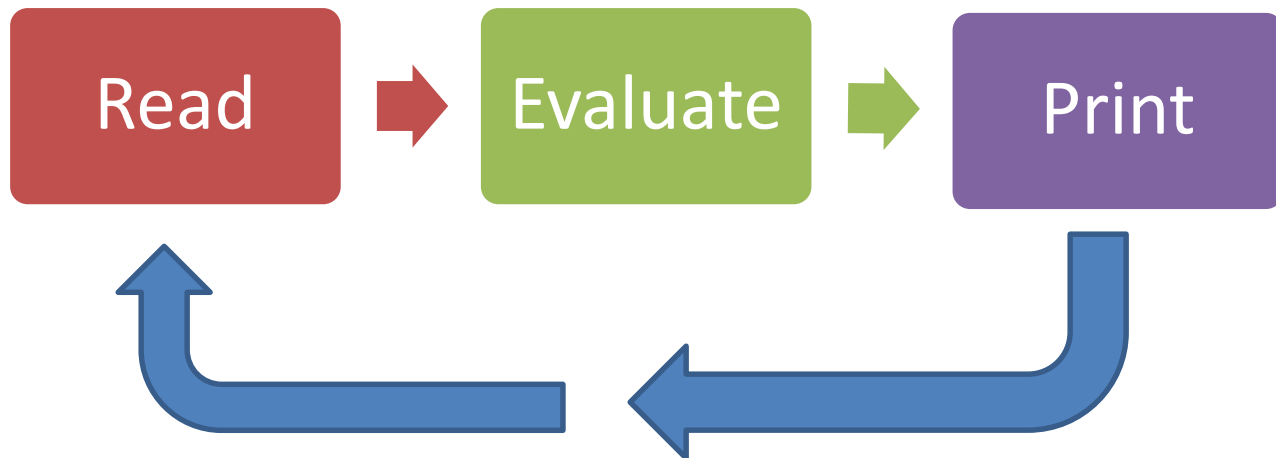

Sample Code…

```
>>>x = 34 - 23          # A comment.
>>>y = "Hello"          # Another one.
>>>z = 3.45
>>>if z == 3.45 or y == "Hello":
        x = x + 1
        y = y + " World"
>>>print(x)
>>>print(y)
```

Enough to Understand

- Assignment uses = and comparison uses ==.

- For numbers +-*/% are as expected.

- Logical operators are words (**and, or, not**)
  not symbols (&&, ||, !).

- The basic printing command is "print."

- First assignment to a variable will create it.

Look at a sample of code...

```
>>>x = 34 - 23              # A comment.
>>>y = "Hello"              # Another one.
>>>z = 3.45
>>>if z == 3.45 or y == "Hello":
       x = x + 1
       y = y + " World"
>>>print(x)
>>>print(y)
```

indentation are important. No braces { } to mark blocks of code in Python. Use consistent indentation instead. The first line with a new indentation is considered outside of the block.

Look at a sample of code…

Start comments with # – the rest of line is ignored.

```
>>>x = 34 – 23
>>>y = "Hello"
>>>z = 3.45
>>>if z == 3.45 or y == "Hello":
        x = x + 1
        y = y + " World"
>>>print(x)
>>>print(y)
```

```
# A comment.
# Another one.
```

indentation are important. No braces { } to mark blocks of code in Python. Use consistent indentation instead. The first line with a new indentation is considered outside of the block.

Variable types

- Dynamic type :

    - Variable types don't need to be declared.

    - Python figures out the variable types on its own.

    - "variables" in python: *object references*, similar to C/C++ pointers.

- Strong Type

    - Python restrictive about how types can be intermingled

    Try x+y, what happened? Error

Variable types

- Examples:
```
>>>pi = 3.1415926
>>>message = "Hello, world"
>>> i = 2+2

>>> type(pi)
>>> type(message)
>>> type(i)

Output:
<type 'float'>
<type 'str'>
<type 'int'>
```

Variable names

- Can contain letters, numbers, and underscores

- Must begin with a letter

- There are some reserved words:

  and, assert, break, class, continue, def, del, elif, else, except, exec, finally, for, from, global, if, import, in, is, lambda, not, or, pass, print, raise, return, try, while

Operators

- \+ addition

- \- subtraction

- / division

- ** exponentiation

- % modulus (remainder after division)

- +=,-=,/=....(No ++ or --)

Operators

- Examples

```
>>> 2*2
>>> 2**3
>>> 10%3
>>> 1.0/2.0
>>> 1/2
```

Output:
4
8
1
0.5
0

Type conversion

- int(), float(), str(), and bool()

- ```
  >>> 1.0/2.0
  >>> 1/2
  >>> float(1)/float(2)
  >>> int(3.1415926)
  >>> str(3.1415926)
  >>> bool(1)
  >>> bool(0)
  ```

- Output:
  ```
  0.5
  0
  0.5
  3
  3.1415926
  True
  False
  ```

Operators acting on strings

- ```
  >>> "NUS!"*3
  'NUS!NUS!NUS!'
  ```

- ```
  >>> "hello " + "world!"
  'hello world!'
  ```

Input from keyboard

- ```
  number = input("Enter Your Lucky Number: ")
  print(number)
  ```

  ```
  name = raw_input("Enter Your loved Pets: ")
  print(name)
  ```

  use help(input) or help(raw_input) to get help from IDLE

Conditionals

- True and False booleans

- Comparison and Logical Operators

- if, elif, and else statements

Booleans: True and False

Things that are False

- The boolean value False
- The numbers 0 (integer), 0.0 (float) and 0j (complex).
- The empty string "".
- The empty list [], empty dictionary {} and empty set set().

Things that are True

- The boolean value True
- All non-zero numbers.
- Any string containing at least one character.
- A non-empty data structure.

boolean expression: evaluated as True or False

Comparison operators

- == : is equal to?

- != : not equal to

- > : greater than

- < : less than

- >= : greater than or equal to

- <= : less than or equal to

- is : do two references refer to the same object?

  - Can "chain" comparisons:
    ```
    >>> a = 49
    >>> 0 <= a <= 99
    True
    ```

Logical operators

- and, or, not

```
>>> 2+2==5 or 1+1==2
True
>>> 2+2==5 and 1+1==2
False
>>> not(2+2==5) and 1+1==2
True
```

- **We do NOT use &&, ||, !**

If Statement

```
>>> ABC = "NUS"
>>> if not ABC:
        print("The ABC string is empty")
```

Must have ":" here

- The "else" case is always optional

Elif Statement

- Equivalent of "else if" in C

- Example:
```
x = 3
if (x == 1):
    print("one")
elif (x == 2):
    print("two")
else:
    print("many")
```

No switch in python

Iteration

- while loops

- for loops

- flow control within loops: break, continue

- range function

While Statement

```
>>> Schools = ["soc", "fass", "eng"]
>>> i = 0
>>> while i<len(Schools)
        print(Schools[i])
    i = i + 1
```

Output:

soc

fass

eng

For Statement

```
>>> Schools = ["soc", "fass", "eng"]
>>> for name in Schools:
        print(name)
>>> for i in range(4):
        print(i)
```

Break, continue

```
>>> for value in [3, 1, 4, 1, 5, 9, 2]:
        print("Checking", value)
        if value > 8:
            print("Exiting for loop")
            break
        elif value < 3:
            print("Ignoring")
            continue
        print("The square is", value**2)
```

Use "break" to stop the for loop

Use "continue" to stop processing the current item

Range()

- creates a list of numbers in a specified range
- range([start,] stop[, step]) -> list of integers

```
>>> range(5)
[0, 1, 2, 3, 4]
>>> range(5, 10)
[5, 6, 7, 8, 9]
>>> range(0, 10, 2)
[0, 2, 4, 6, 8]
```

Datatypes

- Numbers
  - Integer
  - Float
- String

- Collection Data Types: List/Tuple/Dictionary

String basics

- Strings can be delimited by single or double quotes. Multi-line strings use triple-quotes

- An empty string is denoted by having nothing between string delimiters (e.g., '')

- Can access elements of strings with [], with indexing starting from zero:
  >>> "snakes"[3]
  'k'

  Note: can't go other way --- can't set "snakes"[3] = 'p' to change a string; strings are *immutable*

- a[-1] gets the *last* element of string a (negative indices work through the string backwards from the end)

String basics

```
>>> ABC = "hello,NUS"
>>> ABC[0]
'h'
>>> ABC[1]
'e'
>>> ABC[-1]
'S'
>>> ABC[0:5]
'hello'
>>> ABC[1:-1]
'ello,NU'
```

Use "slice" notation to get a substring

ABC[start:end:step]

String basics

Type conversion:
```
>>> int("42")
42
>>> str(20.4)
'20.4'
```

Compare strings with the is-equal operator
```
>>> a = "hello"
>>> b = "hello"
>>> a == b
True
```

- ```
  >>location = "Chattanooga " + "Tennessee"
  >>>Chattanooga Tennessee
  ```

String formatting

- **>>> greeting = "Hello"
  >>> "%s. Welcome to python." % greeting
  'Hello. Welcome to python.'**

- **>>> "The grade for %s is %4.1f" % ("Tom",
  76.051)
  'The grade for Tom is 76.1'**

String methods

- built-in methods for string

- S.capitalize()
- S.center(width)
- S.count(substring [, start-idx [, end-idx]])
- S.find(substring [, start [, end]]))
- S.isalpha(), S.isdigit(), S.islower(), S.isspace(), S.isupper()
- S.join(sequence)
- And many more!

find, split

```
smiles = "C(=N)(N)N.C(=O)(O)O"
>>> smiles.find("(O)")
15
>>> smiles.find(".")
9
>>> smiles.find(".", 10)
-1
>>> smiles.split(".")
['C(=N)(N)N', 'C(=O)(O)O']
```

Use "find" to find the start of a substring.

Start looking at position 10.

Find returns -1 if it couldn't find a match.

Split the string into parts with "." as the delimiter

replace

- Makes a new string with the replacement performed:
  ```
  >>> a = "abcdefg"
  >>> b = a.replace('c', 'C')
  >>> b
  abCdefg
  >>> a
  abcdefg
  ```

in, not in

```
>>>if "Br" in "Brother":
        print("contains brother")

>>>email_address = "clin"
>>>if "@" not in email_address:
        email_address += "@brandeis.edu"
```

Datatypes

- Numbers
  - Integer
  - Float
- String

- Collection Data Types: List/Tuple/Dictionary

Tuples

- A collection of data items which may be of different types.

- Tuples are *immutable*

  ```
  >>>"Tony", "Pat", "Stewart"
  ('Tony', 'Pat', 'Stewart')
  ```

- Python uses () to denote tuples

- An empty tuple is denoted by ()

- Can be used to return multiple values in function call

Tuples

```
>>> yellow = (255, 255, 0) # r, g, b
>>> yellow[1:]
(255, 0)
>>> yellow[0] = 0
Traceback (most recent call last):
File "<stdin>", line 1, in <module>
TypeError: 'tuple' object does not support item assignment
```

Lists

- Like tuples, but *mutable*, and designated by square brackets [] instead of parentheses:
  ```
  >>> [1, 3, 5, 7, 11]
  [1, 3, 5, 7, 11]
  >>> [0, 1, 'boom']
  [0, 1, 'boom']
  ```

- An empty list is []

List Indexing

```
names = ["Ben", "Chen", "Yaqin"]
>>> names[0]
'Ben'
>>> names[3](error)
>>> names[-1]
'Yaqin'
```

Out of range values raise an exception

Tuple also uses "[]" for elements indexing. In list/tuple, they contains *object references*

```
>>>names = ["Ben", "Chen", (1,2,3)]
>>>print(names[2][1])
2
```

List Methods

Use len() to get the length of a list

```
>>> names = ["Ben", "Chen", "Yaqin"]
>>> len(names)
3
```

Append an new item in list

```
>>> x = [1, 2, 3]
>>> x.append("done")
>>> print(x)
  [1, 2, 3, 'done']
```

List Methods

```
>>> ids = ['hello', '2plv', '1crn', '1alm']
>>> del ids[0]
>>> ids
['2plv', '1crn', '1alm']
>>> ids.sort()
>>> ids
['1alm', '1crn', '2plv']
>>> ids.reverse()
>>> ids
['2plv', '1crn', '1alm']
>>> ids.insert(0, "9pti")
>>> ids
['9pti', '2plv', '1crn', '1alm']
```

Dictionaries

- Unordered collections where items are accessed by a key, not by the position in the list

- Collection of arbitrary objects; use object references like lists

- Nestable

- Can grow and shrink in place like lists

- Concatenation, slicing, and other operations that depend on the order of elements do not work on dictionaries

Dictionary

- They map from a "key" to a "value".
  symbol_to_name = {
      'David':'Professor',
      'Sahan':'Postdoc',
      'Shawn':'Grad student'
      }

- Duplicate keys are not allowed
- Duplicate values are just fine
- Keys must be immutable

Dictionary

- **Change in place(*Mutable*)**
  ```
  >>> jobs['Shawn'] = 'Postdoc'
  >>> jobs['Shawn']
  'Postdoc'
  ```

- **Lists of keys and values**
  ```
  >>> jobs.keys()
  ['Sahan', 'Shawn', 'David'] # note order is
  diff
  >>> jobs.values()
  ['Postdoc', 'Postdoc', 'Professor']
  >>> jobs.items()
  [('Sahan', 'Postdoc'), ('Shawn',
  'Postdoc'), ('David', 'Professor')]
  ```

Dictionary

- Delete an entry (by key)
  del d['keyname']

- Add an entry
  d['newkey'] = newvalue

- See if a key is in dictionary
  d.has_key('keyname') or 'keyname' in d

- get() method useful to return value but not fail (return None) if key doesn't exist (or can provide a default value)
  d.get('keyval', default)

Dictionary

- Going through a dictionary by keys:

```
>>>bookauthors = {'Gone': 'Margaret
Mitchell',
                  'Aeneid': 'Virgil',
                  'Odyssey': 'Homer'}
>>>for book in bookauthors:
    print(book, 'by', bookauthors[book])
```
output:
```
Gone by Margaret Mitchell
Aeneid by Virgil
Odyssey by Homer
```

Constructing dictionaries from lists

- If we have separate lists for the keys and values, we can combine them into a dictionary using the zip function and a dict constructor:

```
>>>keys = ['david', 'chris', 'stewart']
>>>values = ['504', '637', '921']
>>>D = dict(zip(keys, vals))
```

Functions

- Defining functions

- Scope

- Return values

Functions

- Define them in the file above the point they're used

```
>>>def square(n):
    return n*n

>>>print("The square of 3 is ", square(3))
```

Output:
```
The square of 3 is  9
```

More about functions

- Arguments are optional. Multiple arguments are separated by commas.

- If there's no return statement, then "None" is returned. Return values can be simple types or tuples. Return values may be ignored by the caller.

- Functions are "typeless" Can call with arguments of any type, so long as the operations in the function can be applied to the arguments.

Scope

- Variables declared in a function do not exist outside that function

- ```
  >>>def square(n):
      m = n*n
      return m
  ```

```
print(m)
```

Output:
```
NameError: name 'm' is not defined
```

Scope

- Variables assigned within a function are local to that function call

- Variables assigned at the top of a module are global to that module; there's only "global" within a module

- Within a function, first search the variable in the local scope, if fail then in global scope (must be declared as "global")

Scope example

```
>>>a = 5              # global

>>>def func(b):
  c = a + b
  return c

>>>func(4)    # gives 4+5=9
>>>c          # not defined
```
Scope example

```
>>>a = 5                 # global

>>>def func(b):
  global c
  c = a + b
  return c

>>>func(4)        # gives 4+5=9
>>>c              # now it's defined (9)
```

Python uses the LEGB rule for variable scoping:

https://www.geeksforgeeks.org/scope-resolution-in-python-legb-rule/

By value / by reference

- Python acts like C's pass by pointer; in-place changes to mutable objects can affect the caller

Example

```
>>>def f1(x,y):
    x = x * 1
    y = y * 2
    print(x, y)            # 0 [1, 2, 1, 2]
>>>def f2(x,y):
    x = x * 1
    y[0] = y[0] * 2
    print(x, y)            # 0 [2, 2]

>>>a = 0
>>>b = [1,2]
>>>f1(a,b)
>>>print a, b              # 0 [1, 2]
>>>f2(a,b)
>>>print(a, b)             # 0 [2, 2]  b is changed
```

Multiple return values

- Can return multiple values as follows:

```
>>>def onetwothree(x):
  return x*1, x*2, x*3

>>>a,b,c = onetwothree(3)
>>>3, 6, 9
```

Default arguments

- can define a function to supply a default value for an argument if one isn't specified

```
>>>def print_error(lineno,
message="error"):
>>>    print("%s at line %d" % (message,
lineno))

>>>print_error(42)
error at line 42
```

Chapter 9: Python Modules

- Basics of modules
- Import and from … import statements
- Changing data in modules
- Reloading modules
- Module packages
- Import as statement

Module basics

- Each file in Python is considered a module. Everything within the file is encapsulated within a namespace (which is the name of the file)

- To access code in another module (file), import that file, and then access the functions or data of that module by prefixing with the name of the module, followed by a period

- Can import user-defined modules or some "standard" modules like sys and random

Python standard library

- There are over 200 modules in the Standard Library:

  - eg: os sys math

- Consult the Python Library Reference Manual, included in the Python installation and/or available at http://www.python.org

import the math module

```
>>> import math
>>> math.pi
```
3.1415926535897931
```
>>> math.cos(0)
```
1.0
```
>>> math.cos(math.pi)
```
-1.0
```
>>> dir(math)
```
['__doc__', '__file__', '__name__', '__package__', 'acos', 'acosh',
'asin', 'asinh', 'atan', 'atan2', 'atanh', 'ceil', 'copysign', 'cos',
'cosh', 'degrees', 'e', 'exp', 'fabs', 'factorial', 'floor', 'fmod',
'frexp', 'fsum', 'hypot', 'isinf', 'isnan', 'ldexp', 'log', 'log10',
'log1p', 'modf', 'pi', 'pow', 'radians', 'sin', 'sinh', 'sqrt', 'tan',
'tanh', 'trunc']

"import" and "from ... import ..."

```
>>> import math
```
math.cos
```
>>> from math import cos, pi
```
cos   #there is no sin, as we only import cos and pi
```
>>> from math import *
```
